METHOD AND APPARATUS FOR OPTICAL TRANSMISSION CONTROL USING COMPENSATING CHANNELS

FIELD OF THE INVENTION

The present invention is directed generally to optical transmission systems. More particularly, the invention relates to controlling optical signal characteristics in optical links including links containing optical amplifiers, such as erbium doped fiber amplifiers ("EDFAs"). This application is a continuation in part of U.S. Patent Application Serial No. 09/317,141 filed May 21, 1999, which is incorporated herein by reference.

BACKGROUND OF THE INVENTION

Digital technology has provided electronic access to vast amounts of information. The increased access has driven demand for faster and higher capacity electronic information processing equipment (computers) and transmission networks and systems to link the processing equipment.

In response to this demand, communications service providers have turned to optical communication systems, which have the capability to provide substantially larger information transmission capacities than traditional electrical communication systems. Information can be transported through optical systems in audio, video, data, or other signal formats analogous to electrical systems. Likewise, optical systems can be used in telephone, cable television, LAN, WAN, and MAN systems, as well as other communication systems.

Early optical transmission systems, known as space division multiplex (SDM) systems, transmitted one information signal using a single wavelength in separate waveguides, i.e. fiber optic strand. The transmission capacity of optical systems was increased by time division multiplexing (TDM) multiple low bit rate, information signals into a higher bit rate signals that can be transported on a single optical wavelength. The low bit

5 rate information carried by the TDM optical signal can then
be separated from the higher bit rate signal following
transmission through the optical system.

10 The continued growth in traditional communications
5 systems and the emergence of the Internet as a means for
accessing data has further accelerated the demand for higher
capacity communications networks. Telecommunications
service providers, in particular, have looked to wavelength
15 division multiplexing (WDM) to further increase the capacity
of their existing systems.

20 In WDM transmission systems, pluralities of distinct
TDM or SDM information signals are carried using
electromagnetic waves having different wavelengths in the
optical spectrum, i.e., far-UV to far-infrared. The
15 pluralities of information carrying wavelengths are combined
into a multiple wavelength WDM optical signal that is
transmitted in a single waveguide. In this manner, WDM
25 systems can increase the transmission capacity of existing
SDM/TDM systems by a factor equal to the number of
wavelengths used in the WDM system.

30 Optical WDM systems were not initially deployed, in
part, because of the high cost of electrical signal
regeneration/amplification equipment required to compensate
for signal attenuation for each optical wavelength
25 throughout the system. The development of the erbium doped
fiber optical amplifier (EDFA) provided a cost effective
means to optically regenerate attenuated optical signal
wavelengths in the 1550 nm range. In addition, the 1550 nm
35 signal wavelength range coincides with a low loss
transmission window in silica based optical fibers, which
40 allowed EDFAs to be spaced further apart than conventional
electrical regenerators.

45 The use of EDFAs essentially eliminated the need for,
and the associated costs of, electrical signal
35 regeneration/amplification equipment to compensate for
signal attenuation in many systems. The dramatic reduction
in the number of electrical regenerators in the systems,

5 made the installation of WDM systems in the remaining
electrical regenerators a cost effective means to increase
optical network capacity.

EDFAs have proven to be a versatile, dependable, and
10 5 cost effective optical amplifier in optical transmission
system. EDFAs can amplify optical signals over a wavelength
range spanning from approximately 1500 nm to 1600 nm. In
addition, the amplification is polarization independent and
15 introduces only low levels of channel to channel crosstalk.

10 However, the characteristics that make EDFAs so useful,
also have some negative side effects. For example, while
EDFAs provide gain over a wavelength range of the WDM
20 signal, the amplification of the each channel varies with
the power of the channel, as well as the total WDM signal
15 power. Therefore, if a channel is added or dropped or a
channel has a power variation, all of the channels will
experience a gain variation that adversely affects the
25 signal quality.

In addition, EDFAs do not equally amplify each channel
20 within the wavelength range. Thus, when channels are added
or dropped or a channel has a power variation, the remaining
30 channels will not only incur gain variations, but the gain
variations will generally be nonuniformly distributed across
the remaining channels.

25 The signal degradation resulting from nonuniform gain
35 variations across the wavelength range is compounded in
systems having cascaded EDFAs as would be expected. The
gain variations, especially in cascaded amplifier chains,
can introduce system instability and noise that results in
40 30 signal distortion, attenuation, and/or loss, and greatly
diminish WDM system performance.

Automatic gain control ("AGC") and automatic power
control ("APC") techniques have been developed to compensate
45 for or suppress channel gain variations in EDFAs. AGC and
35 APC schemes for controlling amplifiers are generally similar
in operation owing to the amplifier relationship that
$$\text{Power}_{\text{OUT}}/\text{Power}_{\text{IN}} = \text{Gain}.$$

AGC and APC schemes can generally be categorized as feedback or feed-forward amplifier control schemes depending upon whether the signal is monitored after passing through the amplifier or before entering the amplifier. A general description of AGC and APC schemes can be found in "Erbium-Doped Fiber Amplifiers, Principles and Applications" by Emmanuel Desurvire (1994), pp. 469-480 ("EDFA94"), which is incorporated herein by reference. A brief, more recent summary is provided in "Dynamic Effects in Optically Amplified Networks", Optical Amplifiers and their Applications ("OAA") July 21-23, 1997, MC4-1-4, ("OAA97-1").

Amplifier control in either scheme is generally achieved by one of two methods. The first method is to control the amplifier gain or power by varying the amplifier pump power in response to the monitored signal, such as described in U.S. Patent No. 4,963,832 and 5,117,196. The second method is to introduce a compensating, or control, signal to control the amplifier gain or power, such as described in U.S. Patent No. 5,088,095 and "Dynamic Gain Compensation in Saturated Erbium-Doped Amplifiers", IEEE Photonics Technology Letters, v3, n5, pp. 453-455 (1991) ("PT91-1").

Feedback control can be based on monitoring one or more signal channels or pilot tones, and/or optical noise at the exit of the amplifier, as described in the above-referenced documents. Further examples of pilot tone monitoring can be found in Electronics Letters, September 14, 1989, v25, n19, pp. 1278-1280, ("EL89-1") and total optical power monitoring can be found more recently in OAA July 11-13, 1996, PDP4-1-5 ("OAA96-1"). In U.S. Patent No. 5,506,724, ASE associated with a counter-propagating compensating/control channel is monitored to provide feedback control over the control channel.

All optical gain control methods are described in Electronics Letters, March 28, 1991, v27, n7, pp. 560-1, ("EL91-1") and U.S. Patent No. 5,239,607. The all optical AGC schemes couple amplified spontaneous emission ("ASE")

5 from the amplifier through a feedback loop, which is
injected into the amplifier input to form a ring laser. The
formation of the ring laser locks the gain of the amplifier
independent of the input power of the signal at other
10 wavelengths.

5 Feedback schemes are generally desirable, because the
schemes can also account for changes that occur in amplifier
performance over time, as well as the input power changes.
15 See "Automatic Gain Control in Cascaded Erbium Doped Fibre
10 Amplifier Systems", Electronics Letters, January 31, 1991,
v27, n3, pp. 193-195, ("EL91-2").

20 Conversely, feed-forward schemes do not inherently
account for variations in amplifier performance. However,
feed-forward schemes in amplifier chains can indirectly
15 account for variations in preceding amplifiers, because the
variations will generally evidence themselves in input power
variations in successive amplifiers.

25 An advantage of feed-forward schemes, as discussed in
PT91-1, is that the schemes can be implemented without
20 feedback from remote amplifier sites. Therefore, feed-
forward control loops can be deployed at logistically
30 convenient locations in a network and operated independently
from the amplifiers, as discussed in EL91-2. Also, feed-
forward schemes allow the WDM signal to be monitored before
25 or after control channels are combined with the optical
signals.

35 As described in EDFA94 (pages 475-6), it is desirable
to control input signal variations at optical switching
nodes in optical networks to equalize signals originating
40 from different stations. Either feedback or feed-forward
control can be provided to control the signal input power.
For example, see Optical Fiber Communication ("OFC")
Conference Technical Digest 1997 TuP4, pp.84-5 ("OFC97-1"),
45 22nd European Conference on Optical Communications 1996
35 ("ECOC96") 5.49-52 and European Patent Application No.
0829981A2.

5 While the signal input can be equalized at each node in
a network, it generally remains necessary to provide
individual amplifier control along an amplifier chain to
10 account for amplifier performance variations. In this
5 regard, EDFA94 (page 472) cautions that "cancellation of
transient saturation is achieved by keeping constant not the
total EDFA input power, but the sum of all input powers
15 weighted by their respective saturation powers". However,
the author concedes that in WDM systems, the required
10 spectral analysis to control amplifiers based on balancing
the amplifier saturation is not practical.

Another shortcoming of current control channel schemes
20 is that the schemes can not be used to protect against large
power variations, which may occur in dense WDM systems.
15 Large increases in the control channel power during gain
transients can produce spectral hole burning in EDFAs that
25 can degrade the system performance to a greater extent than
the gain transients itself. As such, current control
channel schemes have limited applicability in WDM systems.

20 In view of the expanding use of WDM systems and the
desire to perform optical networking, it is becoming
30 increasingly necessary to provide more precise and versatile
amplifier control. The more highly controllable amplifiers
and systems will help drive the further development of high
35 capacity, more versatile, longer distance communication
systems.

BRIEF SUMMARY OF THE INVENTION

40 The apparatuses and methods of the present invention
address the above need for higher performance optical
30 systems. Optical systems of the present invention generally
include an optical signal controller disposed along an
optical link between two optical nodes. The optical signal
45 controller is configured to provide a monitoring signal from
an optical signal passing between the nodes in a plurality
35 of wavelength sub-bands at least one of which includes a
plurality of signal channels. The optical signal controller

5 introduces power in a plurality of compensating channels the
intensity of which is a function of the monitoring signal
power in the plurality of wavelength sub-bands or the total
10 5 optical signal to compensate for power variations in the
signal channels passing between the nodes. In the manner,
the present invention, unlike the prior art, enables the
gain and gain profile of the signal channel over the signal
15 wavelength range to be controlled during transient operation
10 of the system.

In various embodiments, the optical signal controller
can be configured to provide analog or digital control over
20 performance variations that occur in one or more optical
amplifiers in the link. Performance control is achieved by
15 monitoring the input power to the amplifier in two or more
sub-bands of the amplifier wavelength range. The optical
25 signal controller then varies the power of one or more
compensating channels and/or the amplifier power in response
to the monitoring signals to minimize the gain variations
20 within each sub-band.

Compensating, or control, channels can be provided to
30 compensate for input power/gain variations within each of
the sub-bands. The compensating channels can be at
wavelengths within or outside the wavelength range of the
25 compensated sub-band. The compensating channel sources can
35 be responsive to power variations in more than one sub-band.
In various embodiments, the power in two or more
compensating channels can be varied to maintain an average
gain in the remaining signal channels or total optical
40 30 signal power.

The compensating channels can be introduced at nodes,
which include optical components, such as transmit and/or
45 receive terminals, optical routers, switches, and add/drop
devices, or at other monitoring points in the link including
35 amplifier sites. Likewise, the compensating channels can be
removed at various monitoring points and reinserted to

5 provide flexibility in the control of each sub-band throughout the optical link.

In various embodiments, the compensating channels can be used to carry information signals between two points.

10 5 For example, one or more of the compensating channels can be used to carry communication traffic (payload) between nodes and/or monitoring points on the link. In this manner, dedicated add/drop capacity can be provided within the link without sacrificing system signal channel capacity.

15 10 Similarly, one or more of the compensating channels can be used to carry system supervisory information through the link directly between two points.

20 Optical systems of the present invention can include a plurality of nodes and links interconnected optically and/or electrically to form an optical network. The optical systems can also include network management to provide monitoring, provisioning and control of various network nodes and elements, such as amplifiers, etc., wavelength allocation and provisioning in the optical system.

25 20 The controller can generally be operated employing optical - electrical control loops and all-optical loops depending upon the system configuration. In various embodiments, an optical splitter is used to provide the monitoring signal in a wavelength range of interest from the optical signal passing through transmission fiber in the link. In embodiments, the monitoring signal can be provided before or after the insertion of the compensating channels at the input to an amplifier. Alternatively, the power in the sub-bands can be monitored and controlled based on the output of an amplifier.

30 35 The wavelength range can be partitioned into sub-bands based on the gain profile of the optical amplifier(s) being used in the system. Each sub-band monitoring signal can be used to control its corresponding compensating channel source to maintain a gain profile within the sub-bands as the optical signals pass through optical amplifiers. It is generally desirable to partition the wavelength range into

5 sub-bands over which the gain profile of the optical
amplifier(s) is substantially constant or does not greatly
vary. In this manner, the variation in the compensating
10 channel power will generally track the variation of the
5 input signal power in that sub-band.

Compensating channels can be used in combination with
pump control to compensate for input signal variations in
the amplifiers. In some instances, it may be desirable to
15 provide for control in the link using both compensating
10 channels to minimize input power variations and pump
control. Alternatively, the monitoring signals can be used
to control the gain of the amplifier by varying the pump
20 power, drive current, etc. provided to the amplifier.

In an embodiment, the optical signal controller is
15 positioned before a first of one or more EDFAs. The
wavelength range is divided into four contiguous sub-bands
25 spanning the wavelength range of a WDM signal being
amplified in the link. One compensating channel at a
wavelength within each sub-band is used to compensate for
20 gain variation within the sub-band. The compensating
channels are controlled based on the power within the sub-
30 band to substantially compensate for power variations
introduced into the optical link. The compensating channels
of the present invention can also be used in combination
25 with various AGC and APC schemes at the individual
35 amplifiers. The AGC or APC schemes can use either the
signal channels or the compensating channels to control the
amplifier performance.

Thus, the apparatuses and methods of the present
40 30 invention provide for control of the gain profile over a
range of wavelengths in optical transmission systems.
Accordingly, the present invention addresses the
aforementioned problems and provides apparatuses, methods,
45 and optical systems that provide increased control over
35 optical signal characteristics in the system. These
advantages and others will become apparent from the
following detailed description.

BRIEF DESCRIPTION OF THE DRAWINGS

Embodiments of the present invention will now be described, by way of example only, with reference to the accompanying drawings for the purpose of illustrating embodiments only and not for purposes of limiting the same; wherein like members bear like reference numerals and:

Figs. 1-4 show optical systems of the present invention;

Figs. 5-8 show controller embodiments of the present invention; and,

Figs. 9-10 show various optical source embodiments of the present invention.

DESCRIPTION OF THE INVENTION

Fig. 1 shows an embodiment of an optical system 10 including an optical controller 12 positioned to control one or more characteristics of an optical signal passing between two optical processing nodes 14 in an optical link 15. The system 10 can be embodied using one or more serially connected point to point links (Fig. 1) or in a network, which can be configured in various architectures (Fig. 2) and controlled by a network management system 16.

The optical signal controller 12 can be disposed at various monitoring points along transmission media, such as an optical fiber 18, in the optical link 15 between two nodes 14, as shown in Fig. 2. For example, the signal controller 12 can be selectively positioned relative to one or more optical amplifiers 20 disposed along the transmission fiber 18 to control the characteristics of the optical signal being amplified in the link 15.

It is often desirable to position the signal controller 12 at the same physical site as one or more of the nodes 14 at the beginning of the optical link 15. In this configuration, the optical signal characteristics can be controlled through the entire link from a logistically convenient location.

5 As shown in Fig. 3, the optical system 10 will
generally include at least one transmitter 22 for
transmitting optical signals including at least one
10 information carrying signal wavelength λ_i , "signal
5 wavelength or channel", through the optical transmission
fiber 18. Furthermore, the optical system 10 will generally
include at least one optical signal receiver 24 for
receiving the optical signals from the fiber 18. Also, the
15 controller 12 can be included near or within the node 14 as
10 shown in Fig. 3.

The system 10 shown in Fig. 3 can be deployed as a WDM
system including a plurality of transmitters 22_i for
20 providing a plurality of information carrying wavelengths λ_n
to a plurality of receivers 24_j. Wavelength selective or
15 non-selective optical combiners 26 can be used to combine
the optical signals produced by the transmitters 22_i into a
WDM optical signal that is transmitted through the
25 transmission fiber 18. Optical distributors 28 are provided
to distribute, either selectively or non-selectively, the
20 WDM signal to the receivers 24_j.

30 The transmitters 22 used in the system 10 will
generally include a laser optical source, but can include
other coherent as well as suitable incoherent optical
sources as appropriate. Information can be imparted to an
35 optical carrier either by directly modulating a laser or by
external modulating an optical carrier emitted by the laser.
Alternatively, the information can be imparted to an
electrical carrier that can be upconverted onto an optical
40 wavelength to produce the optical signal. Similarly, the
30 optical receiver 24 used in the present invention can
include optical receivers known in the art employing various
detection techniques, such coherent detection, optical
45 filtering and direct detection, and combinations thereof.
Additional versatility in systems 10 configured as networks,
35 such as in Fig. 3, can be provided by employing tunable
transmitters 22 and receivers 24 in the optical nodes 14.

5 An embodiment of the optical signal controller 12, shown in Fig. 3, includes one or more optical compensation sources 30 for providing power in one or more compensating, or control, channel wavelengths λ_{ci} , "compensating
10 channels". The compensating channels are combined with the optical signal channels λ_i via the combiner 26 and transmitted through the fiber 18 in the link 15. The controller 12 also includes an optical distributor 28, such
15 as a low ratio splitter/tap, to provide a monitoring signal within a wavelength range of interest from the optical
10 signal passing through the transmission fiber 18.

The optical combiners 26 and distributors 28 can
20 include wavelength selective and non-selective ("passive"), fiber and free space devices, as well as polarization
15 sensitive devices. Standard or WDM couplers/splitters, circulators, dichroic devices, prisms, gratings, etc., which
25 can be used alone or in combination with various tunable or fixed wavelength transmissive or reflective filters, such as Bragg gratings, Fabry-Perot devices, etc. in various
20 configurations of the optical combiners 26 and distributors 28. Furthermore, the combiners 26 and distributors 28 can
30 include one or more stages incorporating various devices to multiplex, demultiplex, or broadcast signal wavelengths λ_i in the optical systems 10.

35 25 Source controllers 32 are configured to receive the monitoring signal within respective sub-bands and control the optical compensation sources 30 in response to the monitoring signals. Alternatively, the source controllers
40 32 can be configured to control the plurality of
30 compensation sources 30 in response to the total optical signal power or a combination of the sub-band and total powers.

45 The absolute and relative locations where the compensating channels λ_{ci} are introduced into the fiber 18
35 and the monitoring signal is provided from the fiber 18 can be varied as appropriate. The monitoring signal can

5 include both the compensating channels and the signal channels to provide feedback control over the compensating channel powers.

10 Likewise, the compensating channels λ_{ci} can either be removed before or at the end of the link 15 depending upon the system configuration. It is generally desirable to separate and reinsert compensating channels λ_{ci} respectively before and after combining signal channels from different links 15 to provide increased system control and flexibility.

15 The optical signal controller 12 can also be used to transmit communication traffic (payload) and/or system supervisory information via the compensating channels between nodes 14 or various monitoring points within the link 15. When used to transmit communications traffic, transmitters 22 can generally be used as the optical compensating sources 30. It will be appreciated that appropriate modification of the transmitter 22 to provide for variable power in the signal carrying compensating channels may be necessary.

20 Fig. 4 shows an embodiment of the optical system 10 including a plurality of optical signal controller 12 embodiments. The controllers 12 can be embodied as feed-forward or feedback control schemes. The source controller 25 32 can include wavelength selective or non-selective optical to electrical converters to convert the optical monitoring signal to an electrical monitoring signal. For example, the optical to electrical converter can be merely a photodiode 34, or alternatively a fixed or tunable receiver 24, that 40 provides an electrical monitoring signal to the source controller 32. The electrical monitoring signal is used to control one or more optical compensation sources 30 and/or optical amplifiers 20. As shown in Fig. 4, the amplifier 20 45 can include doped, i.e., erbium, or Raman fiber amplifiers 36 supplied with pump energy supplied by a pump source 38, as well as other optical amplifiers including semiconductor amplifiers. The source controller 32 can be configured to

5 control the pump source 38 in response to the monitoring signal.

10 The optical signal controller 12 can be configured to maintain a substantially constant optical signal power
5 distribution in optical links 15. A constant optical power distribution in the links 15, facilitates substantially constant optical amplifier gain performance. Thus, the gain of the individual signal channel being transmitted through
15 the link 15 can be controlled to a substantially constant value, if desired. In addition, the power of the individual
10 signal channels can be controlled to maintain uniform and non-uniform gain profiles over the wavelength range as may be desired.

20 In various embodiments, the optical signal controller
15 12 employs a plurality of compensating channels to maintain a substantially constant gain profile for the optical signal in the link 15. The compensating channel wavelengths λ_{ci}
25 can be within or outside corresponding sub-band wavelength ranges of the optical signals being transmitted in the link
20 15. For example, the wavelength range of the signal channels in the link 15 could be divided into four adjacent sub-bands, each of which include a compensating channel at a
30 wavelength within the sub-band. The compensating channels can be controlled in feed-forward or feedback schemes and
25 can also be used in various AGC and APC schemes used to control the individual amplifiers.

35 The optical signal controller 12 is generally configured to compensate for power changes within the sub-bands of the optical signal before the amplifier gain
40 profile is substantially impacted. For example, the optical signal controller 12 responds to a sudden reduction of the optical power within a sub-band by increasing the optical
45 power supplied by the optical compensating source 30 associated with that sub-band. Likewise, if an increase in
35 optical power is detected in the sub-band, the controller 12 must decrease the optical power output supplied by the compensating source 30 on a similar time scale.

5 The required response time of the controller 12 is a
function of the number of cascaded amplifiers in the link
15. One of ordinary skill will appreciate that the required
response time affects the choice of electronics to practice
10 5 various embodiments of the invention.

 Figs. 5a-5c show exemplary layouts of a digital and
analog sub-band control loops that can be used in the
controller 12 to control the sub-band compensating channel
power. Generally, the controller 12 includes a sub-band
15 demultiplexer 28_a to separate the monitoring signal into
sub-band optical signals. Optical to electrical converters,
such as photodiodes 34, are used to detect the sub-band
optical signal and generate electrical monitoring sub-band
20 input signals S_i. The sub-band source controller 32 uses
15 the electrical monitoring input signals S_i to vary the
compensating channel power provided by the sub-band
compensating source 30 in response to fluctuations in the
sub-band input signal power. A sub-band multiplexer 26_a can
25 be used to combine the compensating channels. A low loss
combiner 26, such as a circulator 40 and Bragg grating 42
20 arrangement, can be used to combine compensating channels
with the WDM signal channel in the transmission fiber 18.

 As further shown in Fig. 5a, the sub-band source
controller 32 will generally include an analog to digital
25 ("A/D") converter 44 to provide the sub-band input signal S_i
35 as a digital signal to a sub-band input comparator
differencing circuit 46. A setpoint power SP_i, which can be
programmable, is provided for each sub-band to the
differencing circuit 46 and a monitor input error E_i is
40 30 generated. The differencing circuit 46 can provide the
absolute error calculated or apply an error threshold to the
calculated error. The error threshold can be programmably
set to minimize jitter or other noise in the signal from
45 causing unnecessary, and possibly destabilizing, power
35 variations in the control loop.

 An error accumulator circuit 48 is used to provide a
digital bias drive signal B_i in response to the monitor

error signal E_i to a digital to analog ("D/A") converter 50 to control the compensating channel power supplied by the sub-band optical source 30. An exemplary error accumulator circuit 48 for a sub-band control loop is shown in Fig. 5b as an overall high-pass filter arrangement. It will be appreciated that other filter arrangements can be used in the error accumulator circuit 48. The arrangement shown in Fig. 5b is configured to drive detected signal channel input power variations to zero by varying the output power of the source 30 in response to the detected variations. The bandwidth of the high-pass filter response generally establishes the length of time during which the control laser output level is perturbed before the correction occurs.

In the error accumulator circuit 48, the setpoint power input error E_i is amplified using a first signal amplifier 52₁ and provided to a summing circuit 56, which accumulates the error. A feedback loop including a second amplifier 52₂ and an addressable memory 54 is used to implement the necessary bias signal value storage function of the error accumulator. The stored bias signal value is fed back to the summing circuit 56. The bias signal can be used to directly vary the output power of the sources 30 and thereby the compensating channel power. Alternatively, the output of the error accumulator circuit 48 can be used to control an external modulator or optical attenuator to vary the compensating channel power being introduced into the transmission fiber 18.

The response of the controller 12 shown in Fig. 5b can be modeled using a sampled-time analysis, where the z-transform of the control loop transfer function can be derived as:

$$B_{out} = B_{in} - B_{out}(G_1/(z - G_2));$$

$$B_{out}/B_{in}(z) = (z - G_2)/(z - (G_2 - G_1)) \text{ and the frequency}$$

$$\text{response is } B_{out}/B_{in}(\omega) = (e^{j\omega T} - G_2)/(e^{j\omega T} - (G_2 - G_1)).$$

B_{in} and B_{out} = input and output bias signal, respectively,

5 G_1 & G_2 = gain of amplifiers 52₁ and 52₂, respectively,

T = sample time,

ω = frequency,

10 $z = e^{j\omega T}$ (transform of the frequency)

5 In the embodiments shown Fig. 5a, a monitoring signal is removed from the input transmission fiber 18₁ after the compensating channel has been inserted into the fiber 18. Thus, the monitoring signal includes both the signal channels and the compensating channels. As previously
10 discussed, the monitoring signal can be removed before the compensating channels are introduced, so as to include only the signal channels, if so desired. Also, the monitoring signal can be passively or actively removed from the fiber in either a wavelength selective or non-selective manner.
15 Typically, the monitoring signal will be removed by employing a low coupling ratio, non-wavelength selective tap coupler to split off a small percentage of the total signal.

20 The control loops can alternatively be implemented as an analog circuit, an example of which is shown in Fig. 5c. The output from the sub-band photodetectors 34₁ are provided to respective analog differencing amplifiers 53₁, either directly or via a fixed or variable attenuator 55₁, which can be used to provide additional control over the sub-band loop. A wideband detector photodiode 34_w can be
30 used to measure the total input power of the monitoring signal. The total input power can be compared to a total power set point in one of the differencing amplifiers 53_w and a total input power correction provided to the sub-band differencing amplifiers 53_v.

35 Similarly, in various digital embodiments generally shown by Fig. 6, the wideband detector photodiode 34_w can also be incorporated to provide a wideband monitoring signal S_w for input power error correction. The electrical sub-band monitoring input signals S_i are summed in another
40 summing circuit 56 into a composite sub-band input signal S_c , which is compared to the wideband monitoring signal S_w in another comparator/differencing circuit 46. An input
45
50

5 offset signal I_s is generated by the differencing circuit 46
and sent to each of the sub-band control loops. A
multiplying circuit 58 allocates the input offset I_s based
on sub-band error allocation setpoints K_i . The input offset
10 I_s can be added to either the sub-band monitoring input
signal S_i or the setpoint power input error signal E_i
depending upon the control loop configuration.

15 A mismatch between the composite sub-band signals S_c
and the wideband detector signal S_w is indicative of
20 variations in the frequency demultiplexer 28_d, the sub-band
detectors 34_s, or the wideband detector 34_w. Error
allocation in the controller 12 can be performed via
numerous algorithms and statically or dynamically allocated
in various distributions depending on the controller 12
15 configuration. For example, individual setpoints K_i and
multiplying circuits 58 can be provided for each sub-band or
a common multiplying circuit 58 can be used to equally
25 distribute various errors in the controller 12.

The signal controller 12 can include one or more
20 central processors 60 to monitor and control the sub-band
control loops. The processors 60 can communicate with the
30 network management system 16 to receive instructions and
provide performance information, such as when non-zero input
offset I_s or other performance variations that occur in the
25 controller 12.

35 Analogous to the input offset monitoring, fault
monitoring and remediation can be provided using an error
distribution loop, as shown in Fig. 7, to redirect sub-band
gain control to other viable loops in the event of a sub-
40 band loop failure. In various embodiments, the set point
input error E_i is compared with the set point power SP_i to
determine whether a sub-band control loop has failed. When
a sub-band control loop failure is detected, a line switch
45 62 passes a failure error signal, typically the set point
35 value SP_i , to another summing circuit 56, which accumulates
the failure error signals from the sub-bands. The control
loop failure determination can be performed using the

5 central processor 60 or a locally employed decision circuit
in the line switch 62. The central processor 60 can also be
used to make appropriate modifications to the correction set
10 points for the remaining control loops depending upon the
5 failure. In addition, the failure determination decision
threshold can be programmably implemented to provide
flexibility in the controller 12.

15 Alternatively, the decision circuit 62 can compare the
input set point SP_i directly with the sub-band input S_i , as
10 in Fig. 8. A common multiplying circuit 58 is also shown in
the embodiment of Fig. 8, in which the error from a failed
sub-band loop is evenly distributed among the surviving
20 loops.

The various errors in the control loops can be
15 distributed using any number of schemes. For example, the
error can be distributed among the surviving sub-band loops
to maintain the gain profile of the optical signal.
25 Alternately, the cumulative failure error signals may be
divided among the remaining loops according to the inverse
20 proportion of the current laser bias of each loop. This
method would lessen the probability that any one of the
surviving sub-band loops would be overloaded upon the
30 failure of an adjacent sub-band loop. The central processor
60 can be used to monitor the redistribution of the error
25 and modify the redistribution to equalize or balance the
power output from the sub-band loops depending upon the
35 channel profile to be maintained.

The accuracy and speed of response of the controller 12
depends on a stable response from the optical compensating
40 30 sources 30 to the bias drive level. The speed and accuracy
of the response will generally vary over time; therefore,
recalibration of the controller 12 will most likely be
required to maintain performance levels.

45 As shown in Fig. 8, one or more of the central
35 processors 60 in the controller 12 can be used to oversee
the operation and perform calibration of the sub-band
control loops. Each control loop can include a calibration

5 device 64 for controlling the drive signal applied to the optical source 30. The calibration device 64 can be a digital device, such as a calibration table, or an analog device, such as a linear circuit.

10 5 During calibration, a switch 66 is used to by-pass the calibration device 64 and allow the central processor 60 to apply one or more test bias signal to the sub-band sources 30. As shown in Fig. 8, the position of the switch 66 will
15 depend on whether an analog or digital calibration device 64 is implemented in the optical signal controller 12. The error distribution loop and fault control techniques
20 previously described will adjust the compensating channel sources 30 that remain in operation to compensate for the variation in the compensating channel from the source 30
15 being calibrated.

25 The optical power of the source 30 can be calibrated by various known methods, for example by using a series of stepped bias levels. An optical spectrum analyzer ("OSA") or other wavelength selective receiver 68 can be used to
20 measure the test output power of the selected source 30 independently of the photodiode 34 associated with a particular sub-band. Alternatively, the test output power
30 can be detected using the sub-band photodiode 34, in the sub-band loop being calibrated. When used in combination, the OSA 68 can be used to calibrate the sub-band photodiode
25 34,, as well as the sub-band source 30 and other components in the sub-band control loop.

35 The detected test output power from either the OSA 68 or sub-band photodiode 34 is fed back to the central
40 30 processor 60 for characterization of the source 30 being calibrated. The characterization can be used to develop a new calibration table for the source 30, which can be implemented when the source 30 is brought back on-line. In
45 this manner, each source 30 in the controller 12 can be calibrated without removing the controller 12 from on-line
35 operation. While it is possible to configure the controller 12 to perform simultaneous multiple calibrations, it is

5 generally not desirable given the power distribution that
may be necessary in the remaining operational sub-band
control loops.

10 In embodiments exemplified in Fig. 8, the OSA 68 is
5 positioned to calibrate the sources 30 based on the sub-band
signal in the transmission fiber 18. It will be appreciated
that the OSA 68 can be included within the controller 12 to
more specifically calibrate the optical sources 30. In some
15 embodiments, it may be possible to substitute the OSA 68 for
10 the wideband photodiode 34, used to determine the sub-band
input power offset.

20 The optical sources 30 used in the present invention
can be conventional diode lasers as known in the art. As
previously discussed, communication traffic or system
15 supervisory information can be sent using the compensating
channel, if an appropriate transmitter 22 is used as the
source 30.

25 The optical sources 30 used in the controller 12
generally have to be capable of operation over a wide power
range to maintain the optical signal gain profile upon the
20 failure of one or more sub-band control loops. The
bandwidth of the source 30 must therefore be sufficiently
30 broad to prevent Stimulated Brillouin Scattering ("SBS")
during high power operation and sufficiently narrow not to
25 interfere with adjacent signal channels. Broad band optical
sources or narrow band sources that have been broadened, via
35 dithering, external cavity gratings, or other techniques,
can be used as the optical sources 30.

40 For example, the optical source 30 can be embodied as
semiconductor optical amplifier ("SOA"), or fiber laser, 70
operated in a lasing mode and stabilized to a desired
wavelength as shown in Fig. 9a-9d. The SOA 70 can provide
compensating channels over a wide power range and Bragg
45 gratings 42, or other reflective elements 78, can be used to
35 control the lasing wavelength and bandwidth. For example,
in Fig. 9a, a high reflectivity Bragg grating 42_H and a
lower reflectivity grating 42_L can be written into fiber

5 pigtails on the SOA 70 to control the lasing wavelength. In
Fig. 9b, a Bragg grating is provided on an output port of a
passive or wavelength selective coupler 72 in a ring
10 configuration with the SOA 70. In various embodiments, the
5 reflective element 78, i.e., Bragg grating 42, can be tuned
to vary the output wavelength of the SOA source 30.

As shown in Figs. 9c-9d, the optical source 30 can
include the SOA 70, or a fiber laser, that is frequency
15 stabilized using a feedback loop incorporating a saturable
10 absorber 74, such as an unpumped erbium fiber. In
embodiments exemplified by Fig. 9c, an external cavity is
formed using a three port circulator 40 in a feedback ring
20 configuration and a wideband reflective device 78. Course
mode selection in the feedback ring can be made using a
15 narrow pass filter 76, such as a Fabry-Perot filter. The
saturable absorber 74 serves to lock the lasing mode of the
SOA 70 or fiber laser within the passband of the filter 76.

25 Similarly, the circulator 40 can be replaced by a
wavelength selective or passive coupler 72 and the SOA 70,
20 or fiber laser, can be incorporated into the ring as shown
in Fig. 9d. Furthermore, an isolator 80 can be employed to
30 provide a unidirectional propagation in the ring
embodiments.

Course wavelength selection in saturable absorber
25 embodiments will generally provide one or more lasing modes
35 within the desired wavelength range, one of which will tend
to become the dominant mode. As the dominant mode or modes
emerge, the saturable absorber 74 will act to prevent mode
hopping because of the high loss associated with modes
40 outside the saturating dominant modes. Also, an external
frequency source can be used in place of the narrow band
filter 76 to select the saturating mode/frequency emitted by
the source 30. The embodiments of Figs. 9a-9d have been
45 described with respect to providing compensating channels,
35 but can also be deployed as fixed or tunable wavelength
optical sources in optical transmitters, local oscillators,
and other optical source applications.

5 In another embodiment, the compensating channel
provided by the optical source 30 can be broadened using
embodiments shown in Figs. 10a&b. For example, the
10 compensating channel can be phase modulated to maintain the
compensating channel power, while broadening the signal by
creating sidebands (Fig. 10a). A phase modulator 82 can be
driven at multiple frequencies to control SBS in fibers
having different core sizes and susceptibilities to SBS.
15 The wavelength of the source 30, such as provided by a DFB
laser, can be controlled using frequency locking devices 84
and schemes as is known in the art. Likewise, narrow band
reflective devices 78, such as narrow band Bragg gratings
20 42, can be employed to further control the wavelength of the
laser.

15 Similarly, the optical source 30, such as a DFB laser,
can be dithered or modulated directly to broaden the
linewidth of the source 30, as shown in Fig. 10b. The
25 amplitude of the dithering or modulating of the laser drive
current can be varied with power to further decrease the
susceptibility to SBS. As in Fig. 10a embodiments, the
20 wavelength of the optical source 30 can be controlled using
various narrow band wavelength selective devices 78, such as
30 Bragg gratings.

Those of ordinary skill in the art will appreciate that
25 numerous modifications and variations that can be made to
specific aspects of the present invention without departing
35 from the scope of the present invention. It is intended
that the foregoing specification and the following claims
cover such modifications and variations.

CLAIMS

What is claimed is:

1. An apparatus comprising:

10

5 an optical signal controller configured to provide a monitoring signal from an optical signal in a plurality of sub-band signals at least one of which includes a plurality of optical signal channels, and control the characteristics of the optical signal based on the sub-band signal characteristics.

15

10 2. The apparatus of claim 1, wherein said optical signal controller is configured to combine a compensating channel having a power based on the sub-band signal powers to control the characteristics of the optical signal.

20

15 3. The apparatus of claim 2, wherein said controller includes a plurality of compensating channel sources providing compensating channels having powers based on the sub-band signal powers.

25

30 4. The apparatus of claim 3, wherein at least one of said plurality of compensating channel sources is configured to compensate for power variations in said other compensating sources.

30

35 5. The apparatus of claim 2, wherein said controller includes at least one compensating channel source for each of the plurality of sub-bands.

35

40 6. The apparatus of claim 5, wherein said controller includes one compensating channel source for each sub-band and each of said compensating sources provides a sub-band compensating channel at a wavelength within the sub-band and the power of the sub-band compensating channel is controlled to maintain an optical signal gain profile within the sub-bands.

40

45

50

55

5 7. The apparatus of claim 2, wherein said controller includes:

 an optical distributor configured to provide the monitoring signal from an optical transmission fiber
10 5 carrying the optical signal;

 a sub-band demultiplexer configured to separate the monitoring signal and provide the plurality of sub-band signals to sub-band control loops, wherein each sub-band
15 control loop includes:

10 an optical to electrical converter configured to receive one of the sub-band signals and provide a sub-band input signal;

20 a sub-band input comparator configured to compare the sub-band input signal power to a set point power level and provide a sub-band input error;

15 a source controller configured to vary the optical power of a sub-band compensating channel provided by a sub-band compensating source in response to the sub-band input error;

25 a multiplexer configured to combine the sub-band compensating channels from said control loops into a compensating channel; and,

30 an optical combiner configured to combine the compensating channel with the optical signal channels in said transmission fiber.
25

35 8. The apparatus of claim 7, wherein said optical combiner combines the compensating channel with the optical signal before said optical distributor provides the monitoring signal.
40

5 9. The apparatus of claim 7, wherein said optical
combiner includes an optical circulator having a first port
configured to receive the compensating channel from said
10 multiplexer, a second port configured to receive the optical
5 signal from an input portion of said transmission fiber and
including at least one reflective element positioned to
reflect the compensating channel back to the second port,
and a third port configured to provide the optical signal
15 and the compensating channel to an output portion of said
10 transmission fiber.

20 10. The apparatus of claim 7, wherein said
demultiplexer is configured to provide a plurality of sub-
band signals in non-overlapping wavelength ranges.

25 11. The apparatus of claim 7, wherein said signal
15 controller includes:
25 a wideband detector configured to receive a portion of
the monitoring signal and provide wideband monitoring
signal;
30 a summing circuit configured to receive a portion of
20 the sub-band input signal and provide a composite sub-band
signal; and,
35 an input offset comparator configured to compare the
composite sub-band signal and the wideband signal and
provide an input offset error to each of said control loops.

40 12. The apparatus of claim 11, wherein said input
25 comparator provides the input offset error equally to each
of said control loops.

45 13. The apparatus of claim 11, wherein said input
comparator provides the input offset error to each of said
30 control loops based on the set point power levels of said
sub-band control loop.

5 14. The apparatus of claim 7, wherein:

 each of said sub-band control loops is configured to
detect a sub-band control loop failure and provide a failure
error signal; and,

10 5 said signal controller includes a fault summing circuit
configured to receive the failure error signal from said
sub-band control loops and provide a cumulative failure
error signal to said sub-band control loops.

15 15. The apparatus of claim 14, wherein the cumulative
10 failure error is distributed to each of the sub-band control
loops and combined with the sub-band input signal.

20 16. The apparatus of claim 14, wherein the cumulative
failure error is distributed to each of the sub-band control
loops and combined with the sub-band input error signal.

25 17. The apparatus of claim 7, wherein said source
controller is configured to calibrate said sub-band source.

30 18. The apparatus of claim 7, wherein said source
controller is configured to apply at least one test bias to
said sub-band source in lieu of said input error, detect a
20 corresponding sub-band compensating channel power provided
by said sub-band source, and calibrate said sub-band source
in response to the detected sub-band compensating channel
35 power.

 19. The apparatus of claim 18, wherein said signal
25 controller includes:

40 an optical spectrum analyzer configured to detect at
least a portion of the sub-band compensating channel from
said sub-band source being calibrated and provide a detected
sub-band compensating channel power; and,

45 30 a central processor configured to receive the detected
sub-band compensating channel power and the corresponding
test bias and provide a sub-band source calibration to said
source controller.

5 20. The apparatus of claim 7, wherein said source
controller is configured to vary the power provided by said
sub-band source by directly modulating the optical power
10 provided by said sub-band source.

5 21. An optical system comprising:
at least two optical nodes configured to pass an
optical signal via an optical transmission fiber between
15 said at least two nodes; and,
an optical signal controller configured to provide a
10 portion of an optical signal as a monitoring signal in a
plurality of sub-band signals at least one of which includes
a plurality of optical signal channels, and control the
20 characteristics of the optical signal based on the sub-band
signal characteristics.

15 22. The optical system of claim 21, wherein said
25 optical signal controller is configured to combine a
compensating channel having a power based on the sub-band
signal powers to control the characteristics of the optical
signal.

30 23. The optical system of claim 21, wherein:
said system includes at least one optical amplifier
disposed along said transmission fiber; and,
35 said optical signal controller is configured to
separate a portion of the optical signal into a plurality of
25 wavelength sub-band signals and combine a compensating
channel having a power sufficient to maintain a gain profile
in the optical signal amplified by said at least one optical
40 amplifier.

30 24. The optical system of claim 23, wherein said
45 signal controller is configured to receive a feedback signal
from said at least one amplifier and control the power of at
least one of the compensating channels.

5 25. The optical system of claim 21, wherein:
 said system includes at least one optical amplifier
 disposed along said transmission fiber; and,
 said optical signal controller is configured to
10 5 separate a portion of the optical signal into a plurality of
 sub-band signals and control the gain profile of the optical
 signal being amplified by said at least one amplifier based
 on the sub-band signal powers.

15 26. The optical system of claim 25, wherein said
10 optical signal controller controls the amplification of the
 optical signals by varying the optical energy supplied by a
 pump source to said at least one amplifier based on the sub-
20 band signal powers.

25 27. The optical system of claim 21, wherein:
15 said system includes at least one optical amplifier to
25 amplify the optical signal within a wavelength range;
 said controller is configured to control variations in
 the amplification of the optical signal over the wavelength
 range by varying the compensating channel powers based on
30 20 the sub-band signal powers.

35 28. The optical system of claim 27, wherein said
 controller is configured to maintain a gain profile in the
 optical signal over the wavelength range.

40 29. The optical system of claim 27, wherein said
25 controller is configured to maintain a gain profile in the
 optical signal in the sub-band wavelength range by varying
 the power of a compensating channel at a wavelength within
 the sub-band wavelength range. .

5 30. The optical system of claim 21, wherein:

a first of said optical nodes includes at least an optical transmitter configured to transmit the optical signal in the optical transmission fiber;

10 5 a second of said optical nodes includes at least an optical receiver configured to receive the optical signal transmitted in said optical transmission fiber; and,

15 at least one optical amplifier disposed along said transmission fiber and configured to amplify the optical signal within a wavelength range; and,

10 said optical signal controller is configured to combine a compensating channel having a power to maintain a constant amplification of the optical signal by said amplifier.

31. The optical system of claim 21, wherein:

15 said system includes a network management system in communication with said signal controller; and,

25 said signal controller includes at least one central processor configured to control said sub-band control loops and communicate with said network management system.

30 20 32. The optical system of claim 21, wherein said nodes include optical components selected from the group consisting of optical transmitters, optical receivers, optical routers, optical add/drop devices, optical switches, and combinations thereof.

25 33. The optical system of claim 21, wherein said signal controller provides a compensating channel carrying at least one of communication signals and system supervisory signals.

30 34. The optical system of claim 33, wherein said controller provides a compensating channel carrying supervisory signals between said nodes.

5 35. A method of controlling optical signal characteristics comprising:
providing an monitoring signal from an optical signal;
10 separating the monitoring signal into a plurality of
5 sub-band signals, one of which includes a plurality of optical signal channels;
controlling the characteristics of the optical signal based on characteristics of the sub-band signals.

15 36. The method of claim 35, wherein said controlling
10 includes:
generating at least one compensating channel to control at least one characteristic of the optical signal based on
20 the at least one characteristic in the sub-band signals;
combining the at least one compensating channel with
15 the optical signal.

25 37. The method of claim 36, wherein:
said method includes amplifying the optical signal;
and,
said generating includes generating a compensating
30 20 channel for each of the sub-band signals to maintain a constant amplification of each channel in the optical signals being amplified.

35 38. The method of claim 37, wherein said controlling includes clamping the gain of at least one compensating
25 channel being amplified.

40 39. The method of claim 36, wherein said generating includes generating at least one compensating channel to maintain a constant power in the optical signal based on the sub-band signal powers.

45 30 40. The method of claim 36, wherein said generating includes generating at least one compensating channel for each of the sub-band signals to maintain a constant power in each sub-band of the optical signal.

INTERNATIONAL SEARCH REPORT

International Application No
PCT/US 00/13953

A. CLASSIFICATION OF SUBJECT MATTER
IPC 7 H04B10/08 H04B10/18 H04J14/02

According to International Patent Classification (IPC) or to both national classification and IPC

B. FIELDS SEARCHED

Minimum documentation searched (classification system followed by classification symbols)
IPC 7 H04B H01S H04J

Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched

Electronic data base consulted during the international search (name of data base and, where practical, search terms used)

EPO-Internal, WPI Data, PAJ, INSPEC

C. DOCUMENTS CONSIDERED TO BE RELEVANT

Category *	Citation of document, with indication, where appropriate, of the relevant passages	Relevant to claim No.
X	EP 0 838 913 A (NORTHERN TELECOM LTD) 29 April 1998 (1998-04-29) column 4, line 29 - line 41 column 6, line 50 - line 52 column 8, line 56 - column 9, line 5 claims 4,5,8,10; figures 1,7 — -/-	1-3, 35, 36

☒ Further documents are listed in the continuation of box C.

☒ Patent family members are listed in annex.

* Special categories of cited documents:

- *A* document defining the general state of the art which is not considered to be of particular relevance
- *E* earlier document but published on or after the international filing date
- *L* document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)
- *O* document referring to an oral disclosure, use, exhibition or other means
- *P* document published prior to the international filing date but later than the priority date claimed

- *T* later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention
- *X* document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone
- *Y* document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art
- *Δ* document member of the same patent family

Date of the actual completion of the international search

16 August 2000

Date of mailing of the international search report

24/08/2000

Name and mailing address of the ISA
European Patent Office, P.O. 5518 Patentlaan 2
